As it can be seen in the first graph, perhaps with some difficulty, is that the percent of arch-dependent packages built
for riscv64 (grey line) has been around or higher than 80% since mid 2018, just a few months after the port was added to the infrastructure.

Given than the arch-dependent packages are about half of the Debian['s main, unstable] archive and that (in simple terms) arch-independent packages can be used by all ports (provided that the software that they rely on is present, e.g. a programming language interpreter), this means that around 90% of packages of the whole archive has been available for this architecture from early on.
